Lecture 21

NoSQL Databases

Week 11

Learning Objectives

- By the end of this session, you should be able to:
  - Define what Big Data is
  - Describe why databases go beyond relational DBs
  - Understand why we need NoSQL
  - Types of NoSQL
  - CAP theorem

The dominance of the relational model

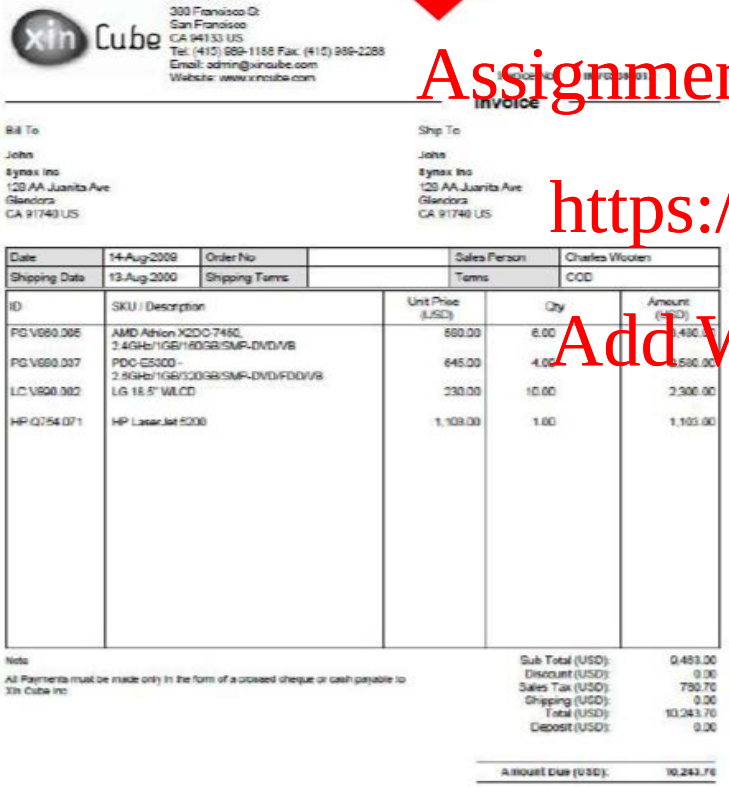
- Pros of relational databases
  - simple, can capture (nearly) any business use case
  - can integrate multiple applications via shared data store
  - standard interface language SQL
  - ad-hoc queries across and within "data aggregates"
  - fast, reliable, concurrent, consistent
- Cons of relational databases
  - Object Relational (OR) impedance mismatch
  - not good with big data
  - not good with clustered/replicated servers

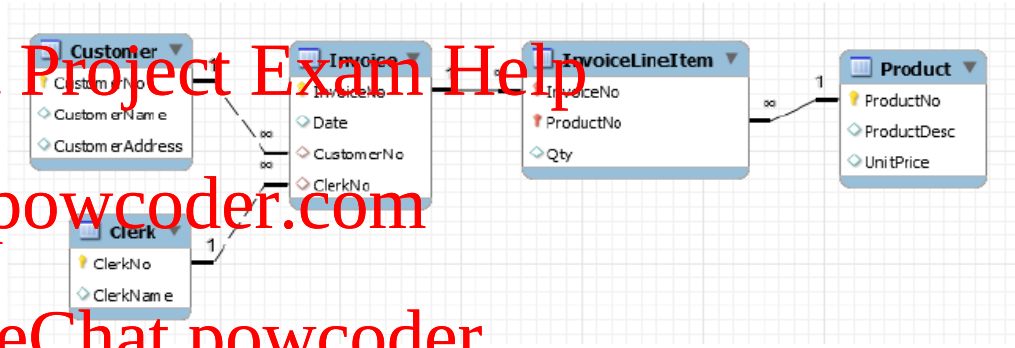
Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

- Adoption of NoSQL driven by “cons” of Relational
- but ‘polyglot persistence‘ = Relational will not go away

But some data is not inherently tabular

One business object (in aggregate form) is stored across many relational tables.





Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

This enables analytical queries like:

```
select productno, sum(qty) from
InvoiceLineItem
group by productno;
```

But there is a lot of work to dissemble and reassemble the aggregate.

Data in Aggregate form: Examples of JSON and XML

JSON Example

```
{"products": [
        {"number": 1, "name": "Zoom X", "Price": 10.00},
        {"number": 2, "name": "Wheel Z", "Price": 7.50},
        {"number": 3, "name": "Spring 10", "Price": 12.75}
]}
```

JavaScript Object Notation

Assignment Project Exam Help

XML Example

eXtensible Markup Language

https://powcoder.com

Add WeChat powcoder

```
<products>
        <product>
                <number>1</number> <name>Zoom X</name> <price>10.00</price>
        </product>
        <product>
                <number>2</number> <name>Wheel Z</name> <price>7.50</price>
        </product>
        <product>
                <number>3</number> <name>Spring 10</name> <price>12.75</price>
        </product>
</products>
```

Big Data and its 3Vs

- Data that exist in very large volumes and many different varieties (data types) and that need to be processed at a very high velocity (speed).
  - **Volume** – a much larger quantity of data than typical for relational databases
  - **Variety** – lots of different data types and formats
  - **Velocity** – data comes at very fast rate (e.g. mobile sensors, web click stream)

Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

Big Data Characteristics

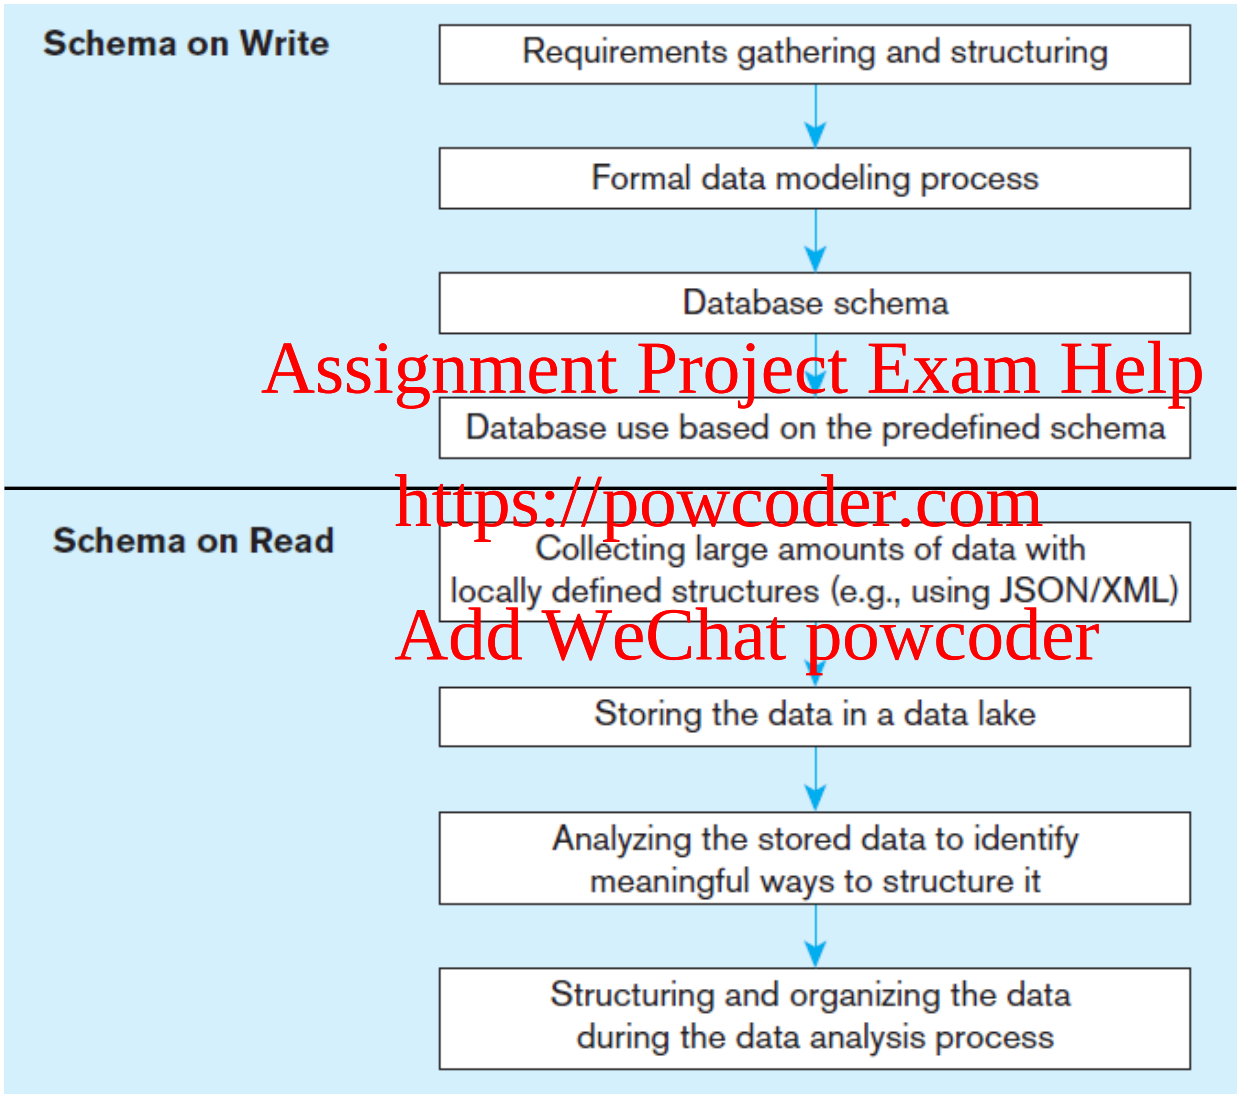
- Schema on Read, rather than Schema on Write
  - Schema on Write– preexisting data model, how traditional databases are designed (relational databases)
  - Schema on Read – data model determined later, depends on how you want to use it (XML, JSON)
  - Capture and store the data, and worry about how you want to use it later

Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

- Data Lake
  - A large integrated repository for internal and external data that does not follow a predefined schema
  - Capture everything, dive in anywhere, flexible access

Jeff Hoffer, Ramesh Venkataraman and Heikki Topi , Modern Database Management: Global Edition

Schema on write vs. schema on read



Traditional database design

The big data approach

NoSQL database properties

- Features
  - Doesn't use relational model or SQL language
  - Runs well on distributed servers
  - Most are open-source
  - Built for the modern web
  - Schema-less (though there may be an "implicit schema")
  - Supports schema on read
  - Not ACID compliant
  - 'Eventually consistent'
- Goals
  - to improve programmer productivity (OR mismatch)
  - to handle larger data volumes and throughput (big data)

from NoSQL Databases: An Overview
by Pramod Sadalage, Thoughtworks(2014)

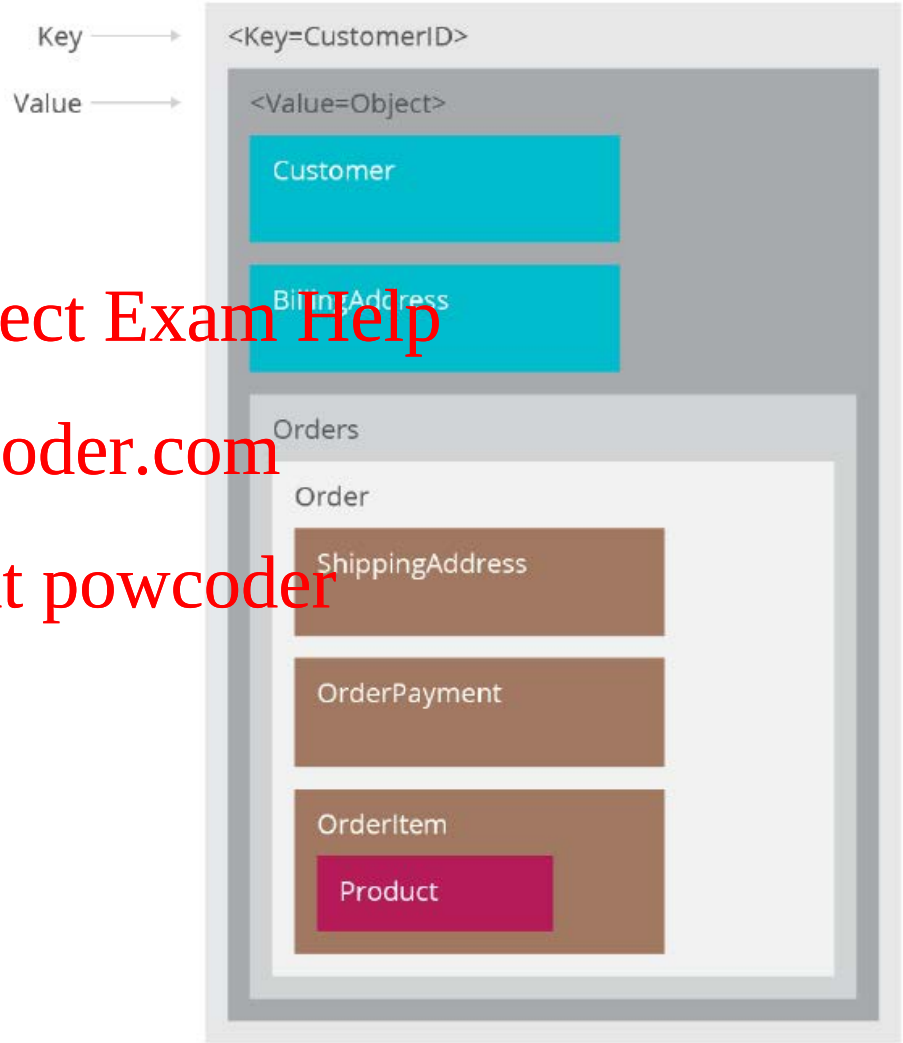
Types of NoSQL databases

Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

(diagram from Martin Fowler)

Types of NoSQL: key-value stores

- Key = primary key
- Value = anything (number, array, image, JSON) –*the application is in charge of interpreting what it means*
- Operations: *Put* (for storing), *Get* and *Update*
- **Examples**: Riak, Redis, Memcached, BerkeleyDB, HamsterDB, Amazon DynamoDB, Project Voldemort, Couchbase



Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

Types of NoSQL: document databases

- Similar to a key-value store except that the document is "examinable" by the databases, so its *content* can be queried, and parts of it updated
- Document = JSON file
- **Examples:** MongoDB, CouchDB, Terrastore, OrientDB, RavenDB

Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

MongoDB Document Structure

- MongoDB documents are composed of field-and-value pairs

```
{
   field1: value1,
   field2: value2,
   field3: value3,
   ...
   fieldN: valueN
}
```

Assignment Project Exam Help

https://powcoder.com

Add WeChat powcoder

```
var mydoc = {
               _id: ObjectId("5099803df3f4948bd2f98391"),
               name: { first: "Alan", last: "Turing" },
               birth: new Date('Jun 23, 1912'),
               death: new Date('Jun 07, 1954'),
               contribs: [ "Turing machine", "Turing test", "Turingery" ],
               views : NumberLong(1250000)
             }
```

MongoDB *document store*

start the mongodb server, then start the mongo shell with "mongo"
show dbs// show a list of all databases
use test// use the database called 'test'
show collections// show all collections in the database 'test'
db.students.insert({name: "Jack", born: 1992})// add a doc to collection
db.students.insert({name: "Jill", born: 1990})// add a doc to collection
db.students.find()// list all docs in students
db.students.find({name: "Jill"})// list all docs where name field = 'Jill'
db.students.update({name: "Jack"}, {$set: {born: 1990}}) // change Jack's year
db.students.remove({born: 1990}) // delete docs where year = 1990

Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

// now insert complex documents from file - note repeating group, no schema
db.students.find().forEach(printjson)// print all docs in neat JSON format
db.students.find({born:1990}, {name: true})// print names for all born in 1990
db.students.update({id:222222}, {$addToSet:
{subjects: {subject: "English", result: "H1"}}})
db.students.find({id:222222}, {_id:false, subjects:true}).forEach(printjson)

Update data deep in hierarchy

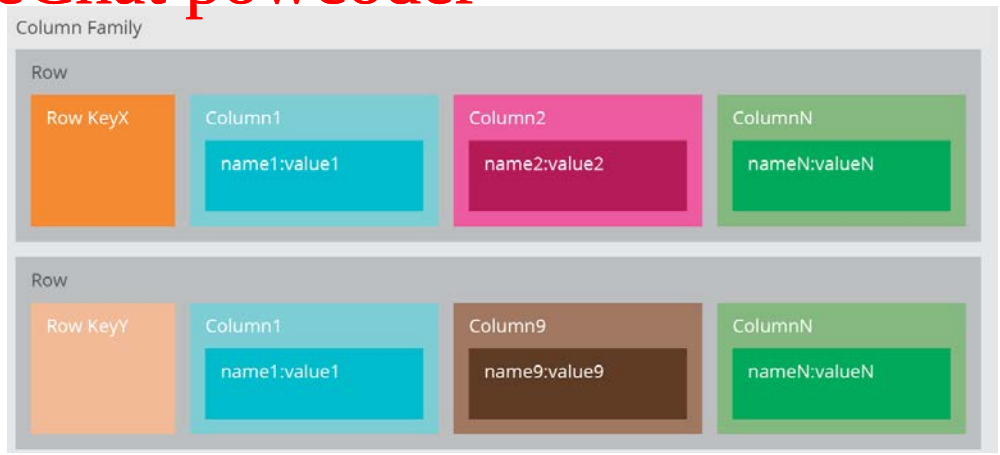
db.students.insert({name: “John", color: “blue”})
// add a new student – different schema but still works

Types of NoSQL: column families

- Columns rather than rows are stored together on disk.
- Makes analysis faster, as less data is fetched.
- This is like automatic vertical partitioning.
- Related columns grouped together into 'families'.
- **Examples**: Cassandra, BigTable, HBase

Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

https://www.youtube.com/watch?v=8KGVFB3kVHQ



Aggregate-oriented databases

- *Key-value*, *document store* and *column-family* are "aggregate-oriented- store business object in its entirety" databases (in Fowler's terminology)

Assignment Project Exam Help

- Pros:
  - *entire* aggregate of data is stored together (no need for transactions)
  - efficient storage on clusters / distributed databases

https://powcoder.com

Add WeChat powcoder

- Cons:
  - hard to analyse across subfields of aggregates
  - e.g. sum over products instead of orders

Types of NoSQL: graph databases

- A ‘graph' is a node-and-arc network
- Social graphs (e.g. friendship graphs) are common examples
- Graphs are difficult to program in relational DB
- A *graph DB* stores entities and their relationships
- Graph queries deduce knowledge from the graph

Assignment Project Exam Help
https://powcoder.com
Add WeChat powcoder

- **Examples**:
  - Neo4J
  - Infinite Graph
  - OrientDBv
  - FlockDB
  - TAO

Table 2-1. Finding extended friends in a relational database versus efficient finding in Neo4j

Depth	RDBMS execution time(s)	Neo4j execution time(s)	Records returned
2	0.016	0.01	~2500
3	30.267	0.168	~110,000
4	1543.505	1.359	~600,000
5	Unfinished	2.132	~800,000

Summary: NoSQL Classifications

- Key-value stores
  - A simple pair of a key and an associated collection of values. Key is usually a string. The database has no knowledge of the structure or meaning of the values.
- Document stores
  - Like a key-value store, but "document" goes further than "value". The document is structured, so specific elements can be manipulated separately.
- Column-family stores
  - Data is grouped in "column groups/families" for efficiency reasons.
- Graph-oriented databases
  - Maintain information regarding the relationships between data items. Nodes with properties.

Distributed data: the CAP theorem

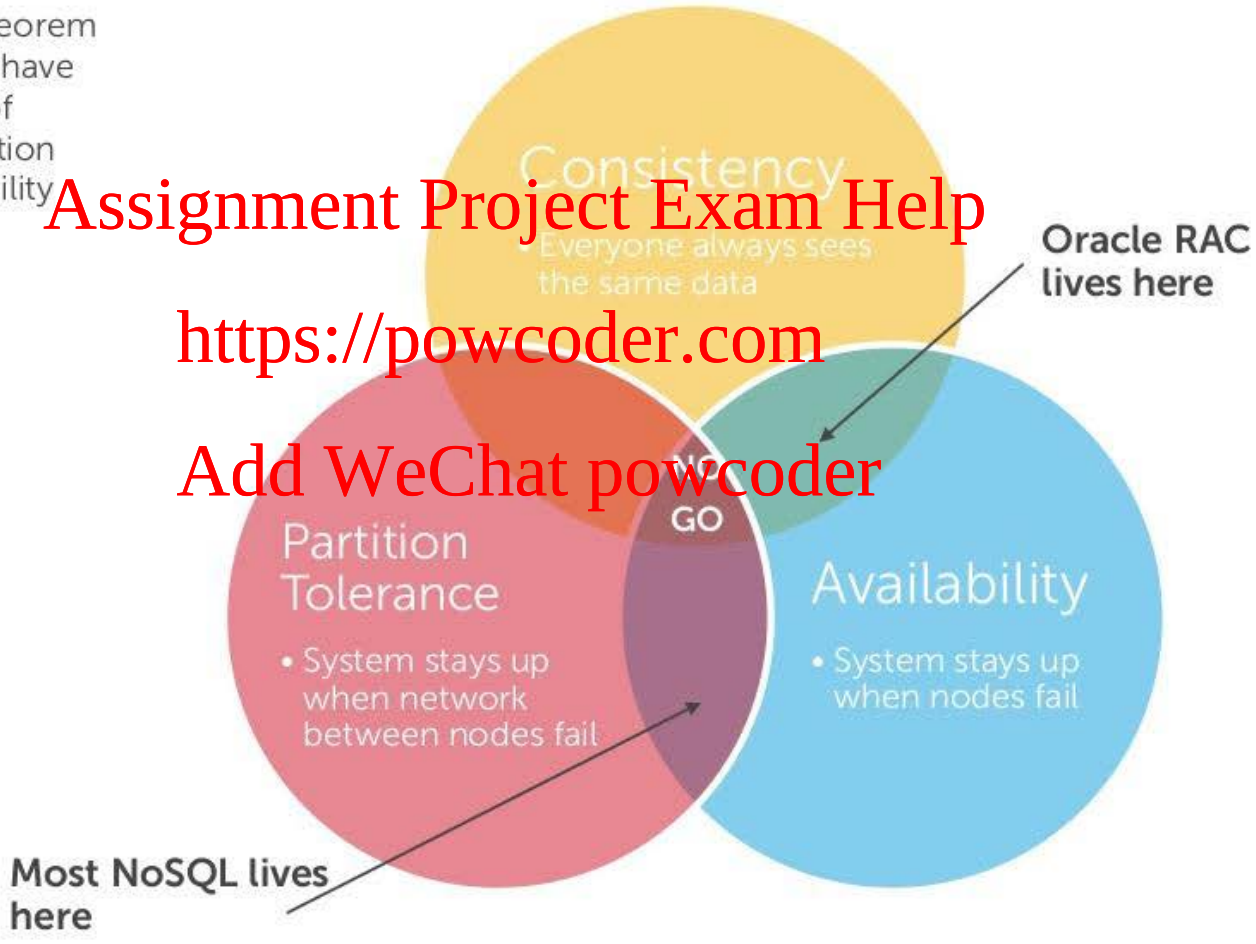
CAP Theorem says something has to give

- CAP (Brewer's) Theorem says you can only have two out of three of Consistency, Partition Tolerance, Availability

Assignment Project Exam Help

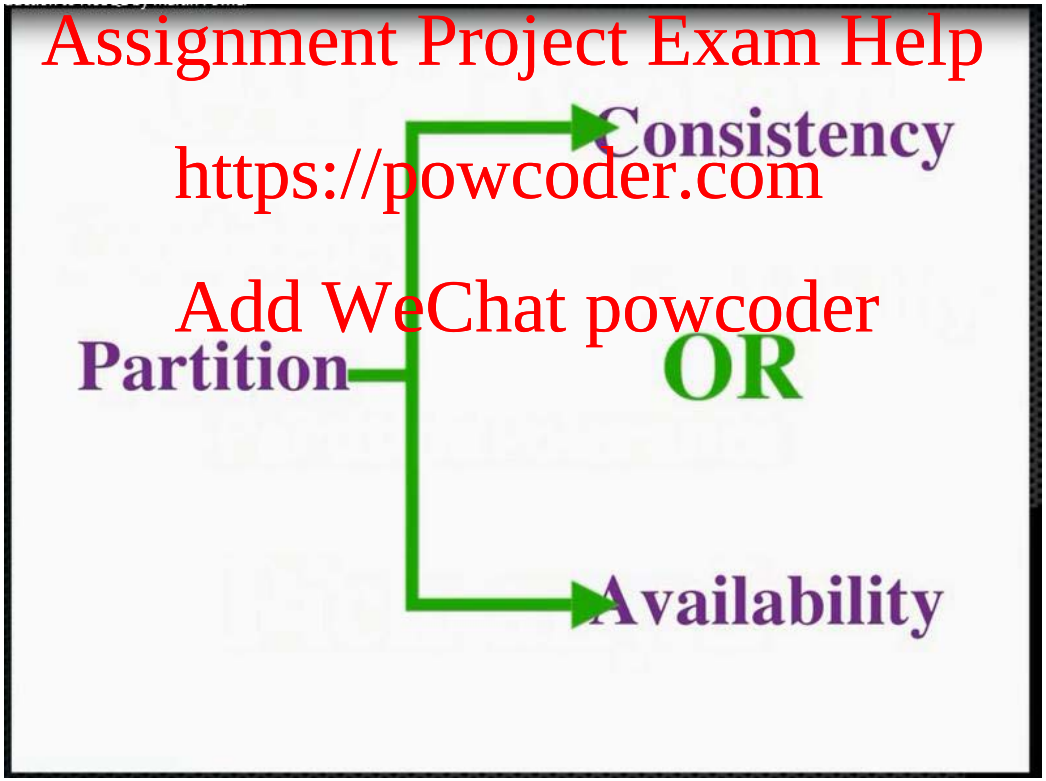
https://powcoder.com

Add WeChat powcoder



CAP theorem: alternative presentation

- Fowler's version of CAP theorem: *If you have a distributed database, when a partition occurs, you must then choose consistency OR availability.*



© University of Melbourne

ACID vs BASE

ACID (Atomic, Consistent, Isolated, Durable)
vs
Base (Basically Available, Soft State, Eventual Consistency)

Assignment Project Exam Help

- **Basically Available**: This constraint states that the system does guarantee the *availability* of the data; there will be a response to any request. But data may be in an *inconsistent* or *changing* state.

https://powcoder.com

- **Soft state**: The state of the system could change over time -even during times without input there may be changes going on due to 'eventual consistency'.

Add WeChat powcoder

- **Eventual consistency**: The system will eventually become consistent once it stops receiving input. The data will propagate to everywhere it needs to, sooner or later, but the system will continue to receive input and is not checking the consistency of every transaction before it moves onto the next one.
